The **TaskFlow p**roject will be demonstrated through an uploaded video demo recording, which will be available via a **YouTube link** shortly.

TaskFlow: A Project Management Platform

Software Life-Cycle

Course Project Overview

TaskFlow is a standalone web application, developed as part of the **TCSS 506** Web Development Course Group Project.

It aims to be a comprehensive project management platform designed specifically for student teams to coordinate group projects, track assignments and enhance collaboration. The application is intended for project group members who are responsible for implementing and verifying the functionality of the web application.

The project emphasizes collaborative planning, design, and deployment of the web application while applying design methodologies to improve the project's modularity.

TaskFlow will utilize MongoDB for database management, React with Typescript for frontend development, Node.js for backend services, and the Flask Python web application framework for development. The application will be deployed on Amazon Web Services (AWS) and will incorporate external APIs for data integration. Additionally, **TaskFlow** will be containerized using Docker to facilitate efficient deployment.

Software Requirements

- The software will run on macOS, Windows, and Linux operating systems with a minimum requirement of 4 GB RAM.
- Node.js 14.x or higher (preferably the latest stable version) is required.
- npm 6.x or higher (preferably the latest stable version) is required.
- Python 3.x or higher (preferably the latest stable version) is required.
- MongoDB for data management (preferably the latest stable version) is required.
- Uses Flask web application framework.

Hardware Requirements

- Monitor (laptop or desktop)
- Keyboard
- Mouse

Pending Decisions

- The choice of additional third-party libraries for enhanced graphics and other functionalities.

- Outstanding decisions regarding the implementation of multiple page content are still pending, which will impact future development.

Special Thanks to:

Professor Ling-Hong Hung for the valuable learnings, guidance, dedication, and wisdom shared during the TCSS 506 course.

TaskFlow
Web Application Project - TCSS 506
Project Overview
This repository contains our group project for TCSS 506 Web Development Course. We've designed and implemented a fully-functional web application with user authentication, database integration, and external API connectivity, deployed using Docker containers on AWS EC2.

Using OAuth 2.0 to Access Google APIs

Note: Use of Google's implementation of OAuth 2.0 is governed by the OAuth 2.0 Policies.

Google APIs use the OAuth 2.0 protocol for authentication and authorization. Google supports common OAuth 2.0 scenarios such as those for web server, client-side, installed, and limited-input device applications.

To begin, obtain OAuth 2.0 client credentials from the Google API Console. Then your client application requests an access token from the Google Authorization Server, extracts a token from the response, and sends the token to the Google API that you want to access. For an interactive demonstration of using OAuth 2.0 with Google (including the option to use your own client credentials), experiment with the OAuth 2.0 Playground.

This page gives an overview of the OAuth 2.0 authorization scenarios that Google supports, and provides links to more detailed content. For details about using OAuth 2.0 for authentication, see OpenID Connect.

Note: Given the security implications of getting the implementation correct, we strongly encourage you to use OAuth 2.0 libraries when interacting with Google's OAuth 2.0 endpoints. It is a best practice to use well-debugged code provided by others, and it will help you protect yourself and your users. For more information, see Client libraries.

Basic steps

All applications follow a basic pattern when accessing a Google API using OAuth 2.0. At a high level, you follow five steps:

1. Obtain OAuth 2.0 credentials from the Google API Console.

Visit the Google API Console to obtain OAuth 2.0 credentials such as a client ID and client secret that are known to both Google and your application. The set of values varies based on what type of application you are building. For example, a JavaScript application does not require a secret, but a web server application does.

You must create an OAuth client appropriate for the platform on which your app will run, for example:

- For server-side or JavaScript web apps use the "web" client type. Do not use this client type for any other application, such as native or mobile apps.
- For Android apps, use the "Android" client type.
- For iOS and macOS apps, use the "iOS" client type.
- For Universal Windows Platform apps, use the "Universal Windows Platform" client type.
- For limited input devices, such as TV or embedded devices, use the "TVs and Limited Input devices" client type.
- For server-to-server interactions, use service accounts.

Page info

On this page

Basic steps
1. Obtain OAuth 2.0 credentials from the Google API Console.
2. Obtain an access token from the Google Authorization Server.
3. Examine scopes of access granted by the user.
4. Send the access token to an API.
5. Refresh the access token, if necessary.

Scenarios
- Web server applications
- Installed applications
- Client-side (JavaScript) applications
- Applications on limited-input devices
- Service accounts

Token size

Refresh token expiration
- Dealing with session control policies for Google Cloud Platform (GCP) organizations

Client libraries

Key Takeaways

AI-GENERATED

- Google APIs use OAuth 2.0 for secure access to user data, requiring applications to obtain credentials and access tokens.
- Different application types have specific OAuth 2.0 flows, including web server, installed, client-side, and service accounts.
- Refresh tokens enable long-term access but can expire due to various factors, such as user revocation or inactivity.
- Service accounts allow server-to-server interactions without user consent using JWTs for authentication.
- Client libraries are available to simplify OAuth 2.0 implementation and ensure security best practices.

Authentication

To securely share credentials within the team:

1. **Never commit .env files** containing actual credentials to the repository
2. Use the provided `.env.example` files as templates
3. Share actual credentials through secure channels:
   - Password manager (LastPass, 1Password, etc.)
   - Encrypted messaging (Signal, WhatsApp)
   - Secure team communication tools (Slack direct messages)
4. Each team member should maintain their own `.env` files with the shared credentials
5. If you need access to credentials, contact one of the team **TaskFlow** members

Running with Docker

```
(venv) parallels@ubuntu-linux-2404:~/Desktop$ sudo usermod -aG docker $USER
(venv) parallels@ubuntu-linux-2404:~/Desktop$ sudo docker run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (arm64v8)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
 $ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:
 https://hub.docker.com/

For more examples and ideas, visit:
 https://docs.docker.com/get-started/

(venv) parallels@ubuntu-linux-2404:~/Desktop$ sudo apt-get update
Get:1 https://download.docker.com/linux/ubuntu noble InRelease [48.8 kB]
```

```
ubuntu@ip-172-31-5-251:~$ docker run hello-world

Hello from Docker!

Amazon Web Services (AWS) *EC2*

EC2

Deployment

```
ubuntu@ip-172-31-5-251:~$ docker run hello-world

Hello from Docker!
This message shows that your installation appears to be working correctly.

To generate this message, Docker took the following steps:
 1. The Docker client contacted the Docker daemon.
 2. The Docker daemon pulled the "hello-world" image from the Docker Hub.
    (amd64)
 3. The Docker daemon created a new container from that image which runs the
    executable that produces the output you are currently reading.
 4. The Docker daemon streamed that output to the Docker client, which sent it
    to your terminal.

To try something more ambitious, you can run an Ubuntu container with:
 $ docker run -it ubuntu bash

Share images, automate workflows, and more with a free Docker ID:

Edit Sprint

Sprints on this board are linked to the Sprints custom field. Changes to sprints are applied to the values that are stored in this field in all of the projects that use this field. Changes are only applied when the owner of the board has permission to update the set of values for this field.

Sprint Name: Sprint 1 - TaskFlow project setup basics

Goal: Setup GitHub repository for the TaskFlow project's version control, TaskFlow SRS Draft, Add Dockerfile and Flask application, Project Approval Meeting,

Schedule: 27 Apr — 10 May

Basic *Commands*

For Python Setup

- *sudo apt-get update*
- *sudo apt-get upgrade*
- *sudo apt install python3-pip*
- *sudo apt install python3.12-venv*
- *python3 -m venv venv*
- *source venv/bin/activate*
- *pip install Flask*

For Docker Installation

- *sudo apt-get install -y apt-transport-https ca-certificates curl software-properties-common*
- *sudo mkdir -p /etc/apt/trusted.gpg.d*
- *curl -fsSL https://download.docker.com/linux/ubuntu/gpg | sudo tee /etc/apt/trusted.gpg.d/docker.gpg > /dev/null*
- *sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/ubuntu $(lsb_release -cs) stable"*
- *sudo apt-get install -y docker-ce*
- *sudo systemctl start docker*
- *sudo systemctl enable docker*
- *sudo usermod -aG docker $USER*
- *sudo docker run hello-world*

For Git and GitHub Setup

- *sudo apt-get install git*
- *git init*
- *git add* **<file_name>**
- *git commit -m* **"Your commit message"**
- *git push origin* **<branch_name>**
- *git status*

Checking Versions

- *flask –version*
- *docker –version*
- *git –version*

Testing

Run tests with:

```
# Backend tests
cd backend
npm test

# Frontend tests
cd frontend
npm test
```

Troubleshooting

MongoDB Connection Issues

- Verify your IP address is in the MongoDB Atlas whitelist
- Check that your username and password are correct
- Ensure the connection string format is correct

Google OAuth Issues

- Verify the correct Google Client ID is in your .env file
- Ensure `http://localhost:3000` is added to authorized JavaScript origins
- Check browser console for any CORS or authorization errors

API Connection Issues

- Verify the backend server is running on port 5000
- Check that CORS is properly configured in the backend
- Ensure the frontend is using the correct API URL
